- Fundamental classes

Oriented Borel-Moore homology

Regular embeddings and l.c.i. morphisms Recall:

A *regular embedding of codimension d* is a closed immersion $i : Z \rightarrow X$ such that \mathcal{I}_Z is locally generated by a regular sequence of length d .

Example A regular embedding of codimension 1 is a Cartier divisor

Definition A morphism $f : Y \rightarrow X$ in \mathbf{Sch}_k is an *l.c.i. morphism* if f can be factored as $p \circ i$, with $i : Y \rightarrow P$ a regular embedding and $p : P \rightarrow X$ smooth and quasi-projective.

$X \in \mathbf{Sch}_k$ is an *l.c.i. scheme* if $X \rightarrow \text{Spec } k$ is an l.c.i. morphism.

$\mathbf{Lci}_k \subset \mathbf{Sch}_k$ is the full subcategory of l.c.i. schemes.

$\mathbf{Sch}'_k :=$ the subcategory of projective morphisms in \mathbf{Sch}_k .

Oriented homology

An *oriented Borel-Moore homology theory* A_* on \mathbf{Sch}_k consists of the following data:

- (D1) An additive functor $A_* : \mathbf{Sch}'_k \rightarrow \mathbf{Ab}_*$, $X \mapsto A_*(X)$.
- (D2) For $f : Y \rightarrow X$ an l.c.i. morphism in \mathbf{Sch}_k , a homomorphism of graded groups $f^* : A_*(X) \rightarrow A_{*-d}(Y)$,
 $d :=$ the codimension of f .
- (D3) For each pair (X, Y) in \mathbf{Sch}_k , a (commutative, associative) bilinear graded pairing $A_*(X) \otimes A_*(Y) \rightarrow A_*(X \times_k Y)$
$$u \otimes v \mapsto u \times v,$$
and a unit element $1 \in A_0(\mathrm{Spec}(k))$.

These satisfy six conditions:

(BM1) $\text{id}_X^* = \text{id}_{A_*(X)}$. For composable l.c.i. morphism f and g ,
 $(f \circ g)^* = g^* \circ f^*$.

(BM2) Given a Tor-independent cartesian square in \mathbf{Sch}_k :

$$\begin{array}{ccc} W & \xrightarrow{g'} & X \\ f' \downarrow & & \downarrow f \\ Y & \xrightarrow{g} & Z, \end{array}$$

with f projective, g l.c.i. . Then $g^* f_* = f'_* g'^*$.

(BM3) For f and g morphisms in \mathbf{Sch}_k : If f and g are projective, then $(f \times g)_*(u \times v) = f_*(u) \times g_*(v)$.
 If f and g are l.c.i. , then $(f \times g)^*(u \times v) = f^*(u) \times g^*(u')$.

(PB) For a line bundle L on $Y \in \mathbf{Sch}_k$ with zero section $s : Y \rightarrow L$ define $\tilde{c}_1(L) : A_*(Y) \rightarrow A_{*-1}(Y)$ by $\tilde{c}_1(L)(\eta) = s^*(s_*(\eta))$.

Let $E \rightarrow X$ be a rank $n + 1$ vector bundle, with associated projective space bundle $q : \mathbb{P}(E) \rightarrow X$. Then

$$\bigoplus_{i=0}^n A_{*+i-n}(X) \xrightarrow{\sum_{i=0}^{n-1} \tilde{c}_1(O(1)_E)^{i \circ q^*}} A_*(\mathbb{P}(E))$$

is an isomorphism.

(EH) Let $p : V \rightarrow X$ be an affine space bundle. Then

$$p^* : A_*(X) \rightarrow A_{*+r}(V)$$

is an isomorphism.

(CD) ***.

Examples (1) The Chow group functor

$$X \mapsto \mathrm{CH}_*(X)$$

with projective push-forward and l.c.i. pull-back given by Fulton.

(2) The Grothendieck group of coherent sheaves

$$X \mapsto G_0(X)[\beta, \beta^{-1}].$$

($\deg \beta = 1$). L.c.i. pull-back exists because an l.c.i. morphism has finite Tor-dimension.

(3) Algebraic cobordism ($\mathrm{char} k = 0$) $X \mapsto \Omega_*(X)$.

L.c.i. pull-backs are similar to Fulton's, but require a bit more work.

Note. There are “refined intersections” for Ω_* , similar to Fulton's refined intersection theory for CH_* .

Homology and cohomology

Every morphism in \mathbf{Sm}/k is l.c.i., hence:

Proposition *Let A_* be an O.B.M.H.T. on \mathbf{Sch}_k . Then the restriction of A to \mathbf{Sm}/k , with*

$$A^n(X) := A_{\dim X - n}(X),$$

defines an O.C.T. A^ on \mathbf{Sm}/k :*

- *The product \cup on $A^*(X)$ is $x \cup y = \delta_X^*(x \times y)$.*
- *$1_X = p_X^*(1)$ for $p_X : X \rightarrow \text{Spec } k$ in \mathbf{Sm}/k .*
- *$c_1(L) = \tilde{c}_1(L)(1_X)$ for $L \rightarrow X$ a line bundle.*

Consequence:

Let A_* be an O.B.M.H.T. on \mathbf{Sch}_k . There is a unique formal group law $F_A \in A_*(k)[[u, v]]$ with

$$F_A(\tilde{c}_1(L), \tilde{c}_1(M))(f_*(1_Y)) = \tilde{c}_1(L \otimes M)(f_*(1_Y))$$

for all $X \in \mathbf{Sch}_k$, all $(f : Y \rightarrow X) \in \mathcal{M}(X)$.

Examples

(1) CH_* has the additive formal group law: $F_{\mathrm{CH}}(u, v) = u + v$

(2) $G_0[\beta, \beta^{-1}]$ has the multiplicative formal group law:

$$F_{G_0}(u, v) = u + v - \beta uv.$$

(3) Ω_* has the universal formal group law: $(F_\Omega, \Omega_*(k)) = (F_{\mathbb{L}}, \mathbb{L}_*)$

Universality and Riemann-Roch

Universality

Theorem Algebraic cobordism Ω_* is the universal O.B.M.H.T. on \mathbf{Sch}_k .

Also:

Theorem The canonical morphism $\vartheta_{\text{CH}} : \Omega_* \otimes_{\mathbb{L}} \mathbb{Z} \rightarrow \text{CH}_*$ is an isomorphism, so CH_* is the universal additive theory on \mathbf{Sch}_k .

A new result (due to S. Dai) is

Theorem The canonical morphism

$$\vartheta_{G_0} : \Omega_* \otimes_{\mathbb{L}} \mathbb{Z}[\beta, \beta^{-1}] \rightarrow G_0[\beta, \beta^{-1}]$$

is an isomorphism, so $G_0[\beta, \beta^{-1}]$ is the universal multiplicative theory on \mathbf{Sch}_k .

Twisting

The τ -twisting construction is modified: one leaves f_* alone and twists f^* by $\widetilde{\text{Td}}_\tau^{-1}(N_f)$:

$$f_{(\tau)}^* = \widetilde{\text{Td}}_\tau^{-1}(N_f) \circ f^*.$$

Here $f : Y \rightarrow X$ is an l.c.i. morphism and $N_f \in K_0(Y)$ is the virtual normal bundle: If we factor f as $p \circ i$, p smooth, i a regular embedding, then:

p has a relative tangent bundle T_p

i has a normal bundle N_i and

$$N_f := [N_i] - [i^*T_p].$$

$\widetilde{\text{Td}}_\tau^{-1}(N_f)$ is the inverse Todd class operator, defined as we did Td_τ^{-1} , using the operators \tilde{c}_1 instead of the classes c_1 .

Riemann-Roch for singular varieties

Twisting $\mathrm{CH}_* \otimes \mathbb{Q}[\beta, \beta^{-1}]$ to give it the multiplicative group law and using Dai's theorem, we recover the Fulton-MacPherson Riemann-Roch transformation $\tau : G_0 \rightarrow \mathrm{CH}_{*,\mathbb{Q}}$:

Using the universal property of $G_0[\beta, \beta^{-1}]$ gives

$$\tau_\beta : G_0[\beta, \beta^{-1}] \rightarrow \mathrm{CH}_* \otimes \mathbb{Q}[\beta, \beta^{-1}]^{(\times)};$$

τ is the restriction of τ_β to degree 0.

Adams operations

J. Malagon-Lopez has used the twisting construction to define Adams operations

$$\psi_k : \Omega_* \rightarrow \Omega_*[1/k]$$

satisfying an “Adams-Riemann-Roch” formula. These recover the classical Adams operations on K_0 and G_0 (after inverting k for ψ_k).

Fundamental classes

Fundamental classes for l.c.i. schemes

Definition Let $p_X : X \rightarrow \text{Spec } k$ be an l.c.i. scheme. For an O.B.M.H.T. A on Sch_k , set

$$1_X^A := p_X^*(1)$$

If X has pure dimension d over k , then 1_X^A is in $A_d(X)$. 1_X is the *fundamental class* of X .

Properties:

- For $X = X_1 \amalg X_2 \in \mathbf{Lci}_k$,
 $1_X = i_{1*}(1_{X_1}) + i_{2*}(1_{X_2})$.
- For $f : Y \rightarrow X$ an l.c.i. morphism in \mathbf{Lci}_k , $f^*(1_X) = 1_Y$.

Fundamental classes of non-l.c.i. schemes

Some theories have more extensive pull-back morphisms, and thus admit fundamental classes for more schemes.

Example Both CH_* and $G_0[\beta, \beta^{-1}]$ admit pull-back for arbitrary *flat* maps, still satisfying all the axioms. Thus, functorial fundamental classes in CH_* and $G_0[\beta, \beta^{-1}]$ exist for *all* $X \in \mathbf{Sch}_k$.

This is NOT the case for all theories.

We give an example for Ω_* .

Let $S_1 \subset \mathbb{P}^5$ be \mathbb{P}^2 embedded by $\mathcal{O}(2)$.

Let $S_2 \subset \mathbb{P}^5$ be $\mathbb{P}^1 \times \mathbb{P}^1$ embedded by $\mathcal{O}(2, 1)$.

Let $R_1 \subset S_1$, $R_2 \subset S_2$ be smooth hyperplane sections. Note:

1. $\deg c_1(\mathcal{O}(2))^2 = \deg c_1(\mathcal{O}(2, 1))^2 = 4$

2. R_1 and R_2 are both \mathbb{P}^1 's

So: R_1 and R_2 are both rational normal curves of degree 4 in \mathbb{P}^4 .

We may assume $R_1 = R_2 = R$.

Let $C(S_1)$, $C(S_2)$ and $C(R)$ be the projective cones in \mathbb{P}^6 .

Proposition *Let A be a O.B.M.H.T. on Sch_k . If we can extend fundamental classes in A for Sm/k to $C(S_1)$, $C(S_2)$ and $C(R)$, functorial for l.c.i. morphisms, then*

$$[\mathbb{P}^2] = [\mathbb{P}^1 \times \mathbb{P}^1] \text{ in } A_2(k)$$

This is NOT the case for $A = \Omega$, since

$$c_2(\mathbb{P}^2) = 3, \quad c_2(\mathbb{P}^1 \times \mathbb{P}^1) = 4.$$

Consequence for Gromov-Witten theory

The formalism of Gromov-Witten theory can be extended to a cobordism valued version, at least if the relevant moduli stack is an **Lci** stack.

One needs a theory of algebraic cobordism for (Deligne-Mumford) stacks: one can make a cheap version with \mathbb{Q} -coefficients by the universal twisting of $CH_{*\mathbb{Q}}$.

BUT: there may be problems in defining the virtual fundamental class for a perfect deformation theory if the intrinsic normal cone of the moduli stack is not **Lci**.

Part B: Cobordism motives

Outline: Part B

- Motives over an O.C.T.
- Cobordism motives
- Motivic computations
- Algebraic cobordism of Pfister quadrics

Motives over an O.C.T.

We follow the discussion of Nenashev-Zainoulline.

A -correspondences

Definition A^* an O.C.T. on \mathbf{Sm}/k . X, Y smooth projective k -varieties. Set

$$\mathrm{Cor}_A^0(X, Y) := A^{\dim Y}(X \times Y).$$

Cor_A^0 is the category with

objects: smooth projective k -varieties \mathbf{SmProj}/k ,

morphisms:

$$\mathrm{Hom}_{\mathrm{Cor}_A^0}(X, Y) := \mathrm{Cor}_A^0(X, Y)$$

and **composition law:**

$$\gamma_{Y,Z} \circ \gamma_{X,Y} := p_{X,Z*}(p_{X,Y}^*(\gamma_{X,Y}) \cdot p_{Y,Z}^*(\gamma_{Y,Z}))$$

- Cor_A^0 is a tensor category: $X \oplus Y = X \amalg Y$ and $X \otimes Y := X \times Y$.
- Sending $f : X \rightarrow Y$ to the “graph”

$$\Gamma_f := (\text{id}_X, f)_*(1_X) \in A^{\dim Y}(X \times Y)$$

gives the functor

$$m_A : \mathbf{SmProj}/k \rightarrow \text{Cor}_A^0.$$

Definition $\mathcal{M}_A^{\text{eff}}$ is the pseudo-abelian hull of Cor_A^0 :

Objects are pairs (X, α) , $\alpha \in \text{End}_{\text{Cor}_A^0}(X)$, $\alpha^2 = \alpha$.

$$\text{Hom}_{\mathcal{M}_A^{\text{eff}}}((X, \alpha), (Y, \beta)) := \beta \text{Hom}_{\text{Cor}_A^0}(X, Y) \alpha$$

with the evident composition.

Definition Let $\text{Cor}_A^*(X, Y) := A^{\dim Y + *}(X \times Y)$.

$\widetilde{\text{Cor}}_A$ is the category with objects pairs (X, n) , X a smooth projective k -variety $n \in \mathbb{Z}$, morphisms

$$\text{Hom}_{\widetilde{\text{Cor}}_A}((X, n), (Y, m)) := \text{Cor}_A^{m-n}(X, Y)$$

Cor_A is the additive category generated by $\widetilde{\text{Cor}}_A$ and \mathcal{M}_A is the pseudo-abelian hull of Cor_A .

For $M = (X, \alpha) \in \mathcal{M}_A^{\text{eff}}$, write $M(m) := ((X, \alpha), m)$.

$\alpha \in \text{Cor}_A^n(X, Y)$ acts as a homomorphism

$$\alpha_* : A^*(X) \rightarrow A^{*+n}(Y).$$

We have ${}^t\alpha \in \text{Cor}_A^{n+\dim X - \dim Y}(Y, X)$; set

$$\alpha^* := {}^t\alpha_* : A^*(Y) \rightarrow A^{*+\dim X - \dim Y + n}(X).$$

- We have $m_A : \mathbf{SmProj}/k \rightarrow \mathbf{Cor}_A$.
- \mathbf{Cor}_A is a tensor category, $1 = m_A(\mathrm{Spec} k)$ and

$$\mathrm{Hom}_{\mathbf{Cor}_A}(1(n), m_A(X)) = A_n(X).$$

- Sending X to $(X, 0)$ defines tensor functors

$$\begin{aligned} \mathbf{Cor}_A^0 &\rightarrow \mathbf{Cor}_A \\ \mathcal{M}_A^{\mathrm{eff}} &\rightarrow \mathcal{M}_A \end{aligned}$$

- A natural transformation of O.C.T.'s on \mathbf{Sm}/k , $\vartheta : A \rightarrow B$, induces tensor functors

$$\begin{aligned} \vartheta_* : \mathbf{Cor}_A^0 &\rightarrow \mathbf{Cor}_B^0 \\ \vartheta_* : \mathcal{M}_A^{\mathrm{eff}} &\rightarrow \mathcal{M}_B^{\mathrm{eff}} \\ \vartheta_* : \mathcal{M}_A &\rightarrow \mathcal{M}_B \end{aligned}$$

We add the ground field k to the notation when necessary:
 $\text{Cor}_A^0(k)$, $\mathcal{M}_A(k)$, etc.

If R is a commutative ring, set

$$\text{Cor}_{A,R}^0 := \text{Cor}_A^0 \otimes R$$

$$\text{Cor}_{A,R} := \text{Cor}_A \otimes R$$

$\mathcal{M}_{A,R}^{\text{eff}}$ and $\mathcal{M}_{A,R}$ are the respective pseudo-abelian hulls.

Examples

(1) For $A^* = \text{CH}^*$, we have the well-known categories:

$\text{Cor}_{\text{CH}}^0(k)$ is the category of correspondences mod rational equivalence, $\mathcal{M}_{\text{CH}}^{\text{eff}}(k)$ is the category of effective Chow motives, $\mathcal{M}_{\text{CH}}(k)$ is the category of Chow motives (all over k).

(2) For $A^* = \Omega^*$, we call $\text{Cor}_{\Omega}^0(k)$ the category of *cobordism correspondences*, $\mathcal{M}_{\Omega}^{\text{eff}}(k)$ the category of *effective cobordism motives*, $\mathcal{M}_{\Omega}(k)$ the category of *cobordism motives* (over k).

(3) We can also take e.g. $A^* = K_0[\beta, \beta^{-1}]$; we write $\text{Cor}_{K_0}^0$, $\mathcal{M}_{K_0}^{\text{eff}}$, etc.

Cobordism motives

Vishik-Yagita have considered the category $\mathcal{M}_{\Omega}^{\text{eff}}(k)$ and discussed its relation with Chow motives.

Remarks

(1) Since Ω^* is universal, there are canonical functors

$$\begin{aligned}\vartheta_*^A &: \text{Cor}_\Omega^0(k) \rightarrow \text{Cor}_A^0(k) \\ \vartheta_*^A &: \mathcal{M}_\Omega^{\text{eff}}(k) \rightarrow \mathcal{M}_A^{\text{eff}}(k)\end{aligned}$$

etc. Thus, identities in $\mathcal{M}_\Omega^{\text{eff}}(k)$ or $\mathcal{M}_\Omega(k)$ yield identities in $\mathcal{M}_A^{\text{eff}}(k)$ or $\mathcal{M}_A(k)$ for all O.C.T.'s A on \mathbf{Sm}/k .

(2) $\Omega^* \otimes \mathbb{Q}$ is isomorphic to the “universal twist” of $\text{CH}^* \otimes \mathbb{L} \otimes \mathbb{Q}$, so one can hope to understand $\mathcal{M}_{\Omega, \mathbb{Q}}$ by modifying $\mathcal{M}_{\text{CH}, \mathbb{L} \otimes \mathbb{Q}}$ by a twisting construction, i.e., a deformation of the composition law. We will see that $\mathcal{M}_{\Omega, \mathbb{Q}}$ is NOT equivalent to $\mathcal{M}_{\text{CH}, \mathbb{L} \otimes \mathbb{Q}}$.

(3) The work of Vishik-Yagita allows one to lift identities in $\mathcal{M}_{\text{CH}}^{\text{eff}}(k)$ or $\mathcal{M}_{\text{CH}}(k)$ to $\mathcal{M}_\Omega^{\text{eff}}(k)$ or $\mathcal{M}_\Omega(k)$

Example [The Lefschetz motive in $\mathcal{M}_{\Omega}^{\text{eff}}$] Let's compare $\text{End}_{\text{Cor}_{\Omega}^0}(\mathbb{P}^1)$ with $\text{End}_{\text{Cor}_{\text{CH}}^0}(\mathbb{P}^1)$

$$\Omega^1(\mathbb{P}^1 \times \mathbb{P}^1) = \mathbb{Z}[0 \times \mathbb{P}^1] \oplus \mathbb{Z}[\mathbb{P}^1 \times 0] \oplus \mathbb{Z}[\mathbb{P}^1] \times [(0, 0)]$$

Set: $\alpha = [0 \times \mathbb{P}^1]$; $\beta = [\mathbb{P}^1 \times 0]$; $\gamma = [\mathbb{P}^1] \cdot [(0, 0)]$.

$\text{Cor}_{\Omega}^0 \rightarrow \text{Cor}_{\text{CH}}^0$ just sends γ to zero. We have the composition laws:

$\text{End}_{\text{Cor}_{\text{CH}}^0}(\mathbb{P}^1)$		
\circ	α	β
α	α	0
β	0	β

$\text{End}_{\text{Cor}_{\Omega}^0}(\mathbb{P}^1)$			
\circ	α	β	γ
α	α	0	0
β	γ	β	γ
γ	γ	0	0

So

$$\text{End}_{\text{Cor}_{\Omega}^0}(\mathbb{P}^1) \rightarrow \text{End}_{\text{Cor}_{\text{CH}}^0}(\mathbb{P}^1) = \mathbb{Z} \times \mathbb{Z}$$

is a non-commutative extension with square-zero kernel (γ) .
Hence:

- The Lefschetz Chow motive $L := (\mathbb{P}^1, \alpha)$ lifts to “the Lefschetz Ω -motive”

$$L_{\Omega}(\lambda) := (\mathbb{P}^1, \alpha + \lambda\gamma)$$

for any choice of $\lambda \in \mathbb{Z}$. Since $[\Delta_{\mathbb{P}^1}] = \alpha + \beta - \gamma$:

$$(\mathbb{P}^1, \text{id}) = (\mathbb{P}^1, \alpha + \lambda\gamma) \oplus (\mathbb{P}^1, \beta - (1 + \lambda)\gamma) \cong L_{\Omega}(\lambda) \oplus 1.$$

Also: $L_{\Omega}(\lambda) \cong L_{\Omega}(\lambda')$ for all λ, λ' , but are not equal as summands of $(\mathbb{P}^1, \text{id})$.

Remark We have seen that

$$\text{End}_{\mathcal{M}_{\Omega}^{\text{eff}}}(m_{\Omega}(\mathbb{P}^1)) \rightarrow \text{End}_{\mathcal{M}_{\text{CH}}^{\text{eff}}}(m_{\text{CH}}(\mathbb{P}^1))$$

is surjective with kernel a square zero ideal. A similar computation shows that

$$\text{End}_{\mathcal{M}_{\Omega}^{\text{eff}}}(m_{\Omega}(\mathbb{P}^n)) \rightarrow \text{End}_{\mathcal{M}_{\text{CH}}^{\text{eff}}}(m_{\text{CH}}(\mathbb{P}^n)) = \prod_{i=1}^n \mathbb{Z}$$

is surjective for all n with $\ker^{n+1} = 0$, but $\ker^n \neq 0$.

Definition Let A be an O.C.T. on \mathbf{Sm}/k , $\vartheta_A : \mathcal{M}_\Omega^{\text{eff}}(k) \rightarrow \mathcal{M}_A^{\text{eff}}(k)$ the canonical functor. Define the *Lefschetz A -motive*

$$L_A := \vartheta_A(L_\Omega).$$

Proposition For $M = (X, \alpha)$, $N = (Y, \beta)$ in $\mathcal{M}_A^{\text{eff}}(k)$,

$$\begin{aligned} \text{Hom}_{\mathcal{M}_A^{\text{eff}}}(M \otimes L_A^{\otimes m}, N \otimes L_A^{\otimes n}) \\ = (\text{id} \times \alpha)^*(\beta \times \text{id})_* A^{\dim Y - m + n}(X \times Y). \end{aligned}$$

Hence

Theorem The inclusion functor $\mathcal{M}_A^{\text{eff}}(k) \rightarrow \mathcal{M}_A(k)$ identifies $\mathcal{M}_A(k)$ with the localization of $\mathcal{M}_A^{\text{eff}}(k)$ with respect to $-\otimes L_A$. Also

$$(X, \alpha)(m) := (X, \alpha, m) \cong (X, \alpha) \otimes L_A^{\otimes m}.$$

The nilpotence theorem

Theorem Take $X, Y \in \mathbf{SmProj}/k$. Then

$$\vartheta_{\mathrm{CH}} : \mathrm{Cor}_{\Omega}^0(X, Y) \rightarrow \mathrm{Cor}_{\mathrm{CH}}^0(X, Y)$$

is surjective. If $X = Y$, then the kernel $\ker(X)$ of ϑ_{CH} is nilpotent.

Proof. Surjectivity: Since $\mathrm{CH}^* = \Omega^* \otimes_{\mathbb{L}} \mathbb{Z}$, $\Omega^*(T) \rightarrow \mathrm{CH}^*(T)$ is surjective for all $T \in \mathbf{Sm}/k$.

Nilpotence of the kernel: $\mathrm{CH}^* = \Omega^* \otimes_{\mathbb{L}} \mathbb{Z} = \Omega^* \otimes (\mathbb{L}/\mathbb{L}^{*<0}) \implies$

$$\ker(X) = \sum_{n>0} \mathbb{L}^{-n} \Omega^{\dim X+n}(X \times X).$$

Composition is \mathbb{L} -linear, hence operates as:

$$\begin{aligned} \mathbb{L}^{-n} \Omega^{\dim X+n}(X \times X) \otimes \mathbb{L}^{-m} \Omega^{\dim X+m}(X \times X) \\ \xrightarrow{\circ} \mathbb{L}^{-n-m} \Omega^{\dim X+n+m}(X \times X). \end{aligned}$$

Also: $\Omega^d(T) = 0$ for $d > \dim T$. Thus

$$\ker(X)^{\circ \dim X+1} = 0.$$

Proposition (Vishik-Yagita)

(1) For $X \in \mathbf{SmProj}/k$, each idempotent in $\mathrm{Cor}_{\mathrm{CH}}^0(X, X)$ lifts to an idempotent in $\mathrm{Cor}_{\Omega}^0(X, X)$.

(2) For M, N in $\mathcal{M}_{\Omega}^{\mathrm{eff}}(k)$, each isomorphism $f : \vartheta_{\mathrm{CH}}(M) \rightarrow \vartheta_{\mathrm{CH}}(N)$ lifts to an isomorphism $\tilde{f} : M \rightarrow N$.

Theorem (Isomorphism) $\vartheta_{\mathrm{CH}} : \mathcal{M}_{\Omega}^{\mathrm{eff}}(k) \rightarrow \mathcal{M}_{\mathrm{CH}}^{\mathrm{eff}}(k)$ and $\vartheta_{\mathrm{CH}} : \mathcal{M}_{\Omega}(k) \rightarrow \mathcal{M}_{\mathrm{CH}}(k)$ both induce bijections on the set of isomorphism classes of objects.

Proof. For $\mathcal{M}^{\mathrm{eff}}$, this follows from the proposition. For \mathcal{M} , this follows by localization.

Note. These results are also valid for motives with R -coefficients, R a commutative ring.

Motivic computations

Elementary computations

- $m_A(\mathbb{P}^n) \cong \bigoplus_{i=0}^n L_A^{\otimes i} \cong \bigoplus_{i=0}^n 1_A(i)$.
- Let $E \rightarrow B$ be a vector bundle of rank $n + 1$, $\mathbb{P}(E) \rightarrow B$ the projective-space bundle. Then

$$m_A(\mathbb{P}(E)) \cong \bigoplus_{i=0}^n m_A(B)(i).$$

- Let $\mu : X_F \rightarrow X$ be the blow-up of X along a codimension d closed subscheme F . Then

$$m_A(X_F) \cong m_A(X) \oplus \bigoplus_{i=1}^{d-1} m_A(F)(i).$$

So:

$$A^*(X_F) \cong A^*(X) \oplus \bigoplus_{i=1}^{d-1} A^{*-d+i}(F).$$

Indeed, we have all these isomorphisms in \mathcal{M}_{CH} , hence in \mathcal{M}_{Ω} by the isomorphism theorem, and thus in \mathcal{M}_A by applying ϑ_A .

Cellular varieties

Definition $X \in \mathbf{SmProj}/k$ is called *cellular* if there is a filtration by closed subsets

$$X = X^0 \supset X^1 \supset \dots \supset X^d \supset X^{d+1} = \emptyset; \quad d = \dim X,$$

such that $\text{codim}_X X^i \geq i$ and either $X^i \setminus X^{i+1} \cong \coprod_{i=1}^{n_i} \mathbb{A}^{d-i}$ or $X^i = X^{i+1}$. If $X_{\bar{k}}$ is cellular, call X *geometrically cellular*.

- For X cellular as above, we have

$$m_A(X) \cong \bigoplus_{i=0}^d \mathbf{1}_A(i)^{n_i}$$

because we have this isomorphism for $A = \text{CH}$.

Examples Projective spaces and Grassmannians are cellular. A smooth quadric over k is geometrically cellular.

Quadratic forms

First some elementary facts about quadratic forms:

- Each quadratic form over k can be diagonalized. If $q = \sum_{i=1}^n a_i x_i^2$, let $Q_q \subset \mathbb{P}^{n-1}$ be the quadric $q = 0$. The *dimension* of q is n .

- For $q_1 = \sum_{i=1}^n a_i x_i^2$, $q_2 = \sum_{j=1}^m b_j y_j^2$, we have the orthogonal sum

$$q_1 \perp q_2 := \sum_{i=1}^n a_i x_i^2 + \sum_{j=1}^m b_j y_j^2$$

and tensor product

$$q_1 \otimes q_2 := \sum_{i=1}^n \sum_{j=1}^m a_i b_j z_{ij}^2.$$

Pfister forms and Pfister quadrics

- For $a \in k^\times$ we have $\langle\langle a \rangle\rangle := x^2 - ay^2$ and for $a_1, \dots, a_n \in k^\times$ the *n-fold Pfister form*

$$\alpha := \langle\langle a_1, \dots, a_n \rangle\rangle := \langle\langle a_1 \rangle\rangle \otimes \dots \otimes \langle\langle a_n \rangle\rangle$$

The quadric $Q_\alpha \subset \mathbb{P}^{2^n-1}$ is the associated *Pfister quadric*.

- The isomorphism class of $\alpha = \langle\langle a_1, \dots, a_n \rangle\rangle$ depends only on the symbol

$$\{a_1, \dots, a_n\} \in k_n(k) := K_n^M(k)/2.$$

$\langle\langle a_1, \dots, a_n \rangle\rangle$ is isomorphic to a hyperbolic form if and only if Q_α is isotropic, i.e. $\langle\langle a_1, \dots, a_n \rangle\rangle = 0$ has a non-trivial solution in k .

The Rost motive

Proposition (Rost) (1) Let $\alpha = \langle\langle a_1, \dots, a_n \rangle\rangle$ and let Q_α be the associated Pfister quadric. Then there is a motive $M_\alpha \in \mathcal{M}_{\text{CH}}^{\text{eff}}(k)$ with

$$m_{\text{CH}}(Q_\alpha) \cong M_\alpha \otimes m_{\text{CH}}(\mathbb{P}^{2^{n-1}-1}).$$

(2) Let \bar{k} be the algebraic closure. There are maps

$$L^{\otimes 2^{n-1}-1} \rightarrow M_\alpha \rightarrow 1$$

which induce

$$M_{\alpha\bar{k}} \cong 1 \oplus L^{\otimes 2^{n-1}-1} \text{ in } \mathcal{M}_{\text{CH}}^{\text{eff}}(\bar{k}).$$

M_α is the *Rost motive*.

The Rost cobordism-motive

Applying the Vishik-Yagita bijection, there is a unique (up to isomorphism) cobordism motive

$$M_\alpha^\Omega \in \mathcal{M}_\Omega^{\text{eff}}(k)$$

with $\vartheta_{\text{CH}}(M_\alpha^\Omega) \cong M_\alpha$. In addition:

1. $m_\Omega(Q_\alpha) \cong M_\alpha^\Omega \otimes m_\Omega(\mathbb{P}^{2^{n-1}-1})$.

2. There are maps $L_\Omega^{\otimes 2^{n-1}-1} \rightarrow M_\alpha^\Omega \rightarrow 1$ which induce

$$M_{\alpha\bar{k}}^\Omega \cong 1 \oplus L_\Omega^{\otimes 2^{n-1}-1} \text{ in } \mathcal{M}_\Omega^{\text{eff}}(\bar{k}).$$

Algebraic cobordism of Pfister quadrics

Vishik-Yagita use the Rost cobordism motive to compute $\Omega^*(Q_\alpha)$.
The computation is in two parts:

1. Compute the image of base-change $\Omega^*(Q_\alpha) \rightarrow \Omega^*(Q_{\alpha\bar{k}})$.
 $\Omega^*(Q_{\alpha\bar{k}})$ is easy because $Q_{\alpha\bar{k}}$ is cellular.
2. Show that $\Omega^*(Q_\alpha) \rightarrow \Omega^*(Q_{\alpha\bar{k}})$ is injective.

Structure of \mathbb{L}

We need some information on \mathbb{L} to state the main result.

Recall the Conner-Floyd Chern classes c_I and the Landweber-Novikov operations s_I . Let $\bar{s}_I(x)$ be the image of $s_I(x)$ in CH^* . For $X \in \mathbf{SmProj}/k$ of dimension $|I|$

$$\bar{s}_I([X]) = \deg c_I(-T_X) \in \mathbb{Z} = \mathrm{CH}^0(k).$$

Since the \bar{s}_I are indexed by the monomials in t_1, t_2, \dots , $\deg t_i = i$, we have

$$\bar{s} : \Omega^*(k) = \mathbb{L}^* \rightarrow \mathbb{Z}[\mathbf{t}]$$

with $\bar{s}([X]) = \sum_I \bar{s}_I(X)t^I = \sum_I c(-T_X)t^I$.

Theorem (Quillen) $\bar{s} : \Omega^*(k) = \mathbb{L}^* \rightarrow \mathbb{Z}[\mathbf{t}]$ is an injective ring homomorphism with image of finite index in each degree.

Definition $I(p) \subset \mathbb{L}^*$ is the prime ideal

$$I(p) := \bar{s}^{-1}(p\mathbb{Z}[\mathbf{t}]).$$

$I(p, n) \subset I(p)$ is the sub-ideal generated by elements of degree $\leq p^n - 1$.

In words: $I(p) \subset \mathbb{L}$ is the ideal generated by $[X]$, $X \in \mathbf{SmProj}/k$ all of whose Chern numbers $\deg c_I(-T_X)$ are divisible by p .

Note. The fact that $s_{2^n-1}(Q_{2^n-1}) \equiv 1 \pmod{2}$ for Q_{2^n-1} a quadric of dimension $2^n - 1$ implies that $I(2, r)$ is the ideal generated by the classes $[Q_{2^n-1}], 0 \leq 2^n - 1 \leq r$ ($[Q_0] = 2 \in \mathbb{L}^0$).

The main theorem

Fix $\alpha := \langle\langle a_1, \dots, a_n \rangle\rangle$, $Q_\alpha \subset \mathbb{P}^{2^n-1}$ the associated Pfister quadric.

Let $h_\Omega^i \in \Omega^i(Q_{\alpha\bar{k}})$ be the class of a codimension i linear section,

Let $\ell_i^\Omega \in \Omega_i(Q_{\alpha\bar{k}})$ be the class of a linear $\mathbb{P}^i \subset Q_{\alpha\bar{k}}$.

h^i, ℓ_i : the images of h_Ω^i and ℓ_i^Ω in CH^i, CH_i .

Since $Q_{\alpha\bar{k}}$ is cellular

$$\Omega^*(Q_{\alpha\bar{k}}) = \bigoplus_{i=0}^{2^{n-1}-1} \mathbb{L} \cdot h_\Omega^i \oplus \mathbb{L} \cdot \ell_i^\Omega.$$

Theorem *The base-change map $p^* : \Omega^*(Q_\alpha) \rightarrow \Omega^*(Q_{\alpha\bar{k}})$ is injective and the image of p^* is*

$$\bigoplus_{i=0}^{2^{n-1}-1} \mathbb{L} \cdot h_\Omega^i \oplus I(2, n-2) \cdot \ell_i^\Omega$$

Idea of proof:

Use the isomorphisms

$$m_{\Omega}(Q_{\alpha}) \cong M_{\alpha}^{\Omega} \otimes m_{\Omega}(\mathbb{P}^{2^{n-1}-1}), \quad M_{\alpha k}^{\Omega} \cong 1 \oplus L_{\Omega}^{2^{n-1}-1}$$

to show that the image of base-change is $\bigoplus_{i=0}^{2^{n-1}-1} \mathbb{L} \cdot h_{\Omega}^i \oplus J \cdot \ell_i^{\Omega}$ for some ideal $J \subset \mathbb{L}$.

A result of Rost on M_{α}^{CH} plus Vishik-Yagita lifting shows that

$$M_{\alpha}^{\Omega} \oplus ? = m_{\Omega}(P_{\alpha}),$$

P_{α} : a linear section of Q_{α} of dimension $2^{n-1} - 1$.

The “small” dimension ($\leq 2^{n-1} - 1$) of P_{α} allows one to show that $J = I(2, n - 2)$.

The injectivity is handled by the fact that P_{α} splits M_{α} .
